

ML-Basics Learner

- Understand that a supervised learner fits models automatically from training data

-

SUPERVISED LEARNING EXAMPLE

Imagine we want to investigate how working conditions affect productivity of employees.

- It is a **regression** task since the target *productivity* is continuous.
- We collect data about worked minutes per week (*productivity*), how many people work in the same office as the employee in question, and the employee's salary.

Features x		Target y
People in Office (Feature 1) x_1	Salary (Feature 2) x_2	Worked Minutes Week (Target Variable)
4	4300 €	2220
12	2700 €	1800
5	3100 €	1920

Diagram illustrating the data structure for a regression problem. The data is organized into a table with 3 rows (labeled $n = 3$) and 3 columns. The first two columns represent features x (labeled $p = 2$), and the third column represents the target variable y .

- Feature 1 (x_1):** People in Office. Values: 4, 12, 5.
- Feature 2 (x_2):** Salary (in €). Values: 4300 €, 2700 €, 3100 €.
- Target Variable (y):** Worked Minutes Week. Values: 2220, 1800, 1920.

The diagram also shows the mapping of individual features to their respective variables in the input vector x and target vector y :

- $x_1^{(2)}$ points to the first feature column.
- $x_2^{(1)}$ points to the second feature column.
- $y^{(3)}$ points to the target column.

SUPERVISED LEARNING EXAMPLE / 2

How could we construct a model from these data?

We could investigate the data manually and come up with a simple, hand-crafted rule such as:

- The baseline productivity of an employee with salary 3000 and 7 people in the office is 1850 minutes
- A decrease of 1 person in the office increases productivity by 30
- An increase of the salary by 100 increases productivity by 10

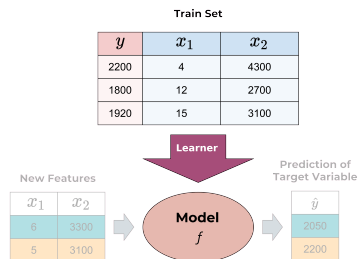

=> Obviously, this is neither feasible nor leads to a good model

LEARNER DEFINITION

- The algorithm for finding our f is called **learner**. It is also called **learning algorithm** or **inducer**.
- We prescribe a certain hypothesis space, the learner is our means of picking the best element from that space for our data set.
- Formally, it maps training data $\mathcal{D} \in \mathbb{D}$ (plus a vector of **hyperparameter** control settings $\lambda \in \Lambda$) to a model:

$$\mathcal{I} : \mathbb{D} \times \Lambda \rightarrow \mathcal{H}$$

LEARNER DEFINITION / 2

As pseudo-code template it would work like this:

- Learner has a defined model space of parametrized functions \mathcal{H} .
- User passes data set $\mathcal{D}_{\text{train}}$ and control settings λ .
- Learner sets parameters so that model matches data best.
- Optimal parameters $\hat{\theta}$ or function \hat{f} is returned for later usage.
