Solution 1: SVM - Regression

- (a) Regarding the values of $d_{\epsilon}(f(\cdot \mid \theta_0, \boldsymbol{\theta}), \mathbf{x}^{(i)})$ for an outcome $y^{(i)}$ we have that:
 - If $y^{(i)}$ is within the ϵ -tube around $f(\mathbf{x}^{(i)} \mid \theta_0, \boldsymbol{\theta})$, then $d_{\epsilon} \left(f(\cdot \mid \theta_0, \boldsymbol{\theta}), \mathbf{x}^{(i)} \right) \geq 0$. The largest possible value of $d_{\epsilon} \left(f(\cdot \mid \theta_0, \boldsymbol{\theta}), \mathbf{x}^{(i)} \right)$ is ϵ , which corresponds to a perfect prediction for that point, i.e., $y^{(i)} = f(\mathbf{x}^{(i)} \mid \theta_0, \boldsymbol{\theta})$.
 - If $y^{(i)}$ is not within the ϵ -tube around $f(\mathbf{x}^{(i)} \mid \theta_0, \boldsymbol{\theta})$, then $d_{\epsilon}(f(\cdot \mid \theta_0, \boldsymbol{\theta}), \mathbf{x}^{(i)}) < 0$.

A desirable choice of the parameters $(\theta_0, \boldsymbol{\theta})^{\top}$ with respect to γ_{ϵ} would be such that γ_{ϵ} is maximized, as this would make sure that the prediction errors are as far away as possible from the ϵ -boundaries, but still within the ϵ -tube.

The choice of the parameters $(\theta_0, \boldsymbol{\theta})^{\top}$ is not unique, as the plot on the right shows for $\epsilon = 0.5$. Both the black and the green model have $\gamma_{\epsilon} = \epsilon$, since $d_{\epsilon}(f(\cdot \mid \theta_0, \boldsymbol{\theta}), -0.2) = \epsilon = d_{\epsilon}(f(\cdot \mid \theta_0, \boldsymbol{\theta}), 0)$ and we cannot find another model such that its ϵ -tube covers the outcomes.

(b) We formulate the desired property of a maximal γ_{ϵ} as an optimization problem:

$$\max_{\boldsymbol{\theta}, \theta_0} \quad \gamma_{\epsilon}$$
s.t.
$$d_{\epsilon} \left(f(\cdot \mid \theta_0, \boldsymbol{\theta}), \mathbf{x}^{(i)} \right) \ge 0 \quad \forall i \in \{1, \dots, n\}.$$

The constraints mean that we require that any instance i should have a positive ϵ -distance of the prediction error for $f(\mathbf{x}^{(i)} \mid \theta_0, \boldsymbol{\theta})$. In other words, the differences between the predictions and the outcomes should be at most ϵ and within the ϵ -tube of the predictions. The latter optimization problem can be rewritten as

$$\max_{\boldsymbol{\theta}, \theta_0} \quad \gamma_{\epsilon}$$
s.t.
$$\epsilon - |y^{(i)} - \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} - \theta_0| \ge 0 \quad \forall i \in \{1, \dots, n\}.$$

And further to

$$\max_{\boldsymbol{\theta}, \boldsymbol{\theta}_0} \quad \gamma_{\epsilon}$$
s.t.
$$\epsilon - y^{(i)} + \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} + \theta_0 \ge 0 \quad \forall i \in \{1, \dots, n\}$$
and
$$\epsilon + y^{(i)} - \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} - \theta_0 \ge 0 \quad \forall i \in \{1, \dots, n\}.$$

As we have seen before the solution might not be unique, so that we make the reference choice $\gamma_{\epsilon} = C/\|\boldsymbol{\theta}\|$ for some constant C > 0, leading to

$$\min_{\boldsymbol{\theta}, \theta_0} \quad C \|\boldsymbol{\theta}\|^2$$
s.t.
$$\epsilon - y^{(i)} + \boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0 \ge 0 \quad \forall i \in \{1, \dots, n\}$$
and
$$\epsilon + y^{(i)} - \boldsymbol{\theta}^\top \mathbf{x}^{(i)} - \theta_0 \ge 0 \quad \forall i \in \{1, \dots, n\}.$$

For sake of convenience, we set the constant to $\frac{1}{2}$.

(c) The Lagrange function of the SVM optimization problem is

$$L(\boldsymbol{\theta}, \theta_0, \boldsymbol{\alpha}, \tilde{\boldsymbol{\alpha}}) = \frac{1}{2} \|\boldsymbol{\theta}\|^2 - \sum_{i=1}^n \alpha_i \left[\epsilon - y^{(i)} + \left(\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0 \right) \right] - \sum_{i=1}^n \tilde{\alpha}_i \left[\epsilon - \left(\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0 \right) + y^{(i)} \right]$$

s.t.
$$\alpha_i, \tilde{\alpha}_i \ge 0 \quad \forall i \in \{1, \dots, n\}.$$

The dual form of this problem is

$$\max_{\boldsymbol{\alpha}, \tilde{\boldsymbol{\alpha}}} \min_{\boldsymbol{\theta}, \theta_0} L(\boldsymbol{\theta}, \theta_0, \boldsymbol{\alpha}, \tilde{\boldsymbol{\alpha}}).$$

(d) The stationary points of L can be derived by setting the derivative of the Lagrangian function to 0 and solve with respect to the corresponding term of interest, i.e., for θ :

$$\nabla_{\boldsymbol{\theta}} L(\boldsymbol{\theta}, \theta_0, \boldsymbol{\alpha}, \tilde{\boldsymbol{\alpha}}) = \boldsymbol{\theta} - \sum_{i=1}^{n} \alpha_i \mathbf{x}^{(i)} + \sum_{i=1}^{n} \tilde{\alpha}_i \mathbf{x}^{(i)} \stackrel{!}{=} 0$$
$$\Leftrightarrow \boldsymbol{\theta} = \sum_{i=1}^{n} (\alpha_i - \tilde{\alpha}_i) \mathbf{x}^{(i)}.$$

and for θ_0 :

$$\nabla_{\theta_0} L(\boldsymbol{\theta}, \theta_0, \boldsymbol{\alpha}, \tilde{\boldsymbol{\alpha}}) = -\sum_{i=1}^n \alpha_i + \sum_{i=1}^n \tilde{\alpha}_i \stackrel{!}{=} 0$$

$$\Leftrightarrow 0 = \sum_{i=1}^n (\alpha_i - \tilde{\alpha}_i).$$

If $(\theta, \theta_0, \boldsymbol{\alpha}, \tilde{\boldsymbol{\alpha}})$ fulfills the KKT conditions (stationarity, primal/dual feasibility, complementary slackness), it solves both the primal and dual problem (strong duality). Under these conditions, and if we solve the dual problem and obtain $\hat{\boldsymbol{\alpha}}$ or $\tilde{\boldsymbol{\alpha}}$, we know that $\boldsymbol{\theta}$ is a linear combination of our data points:

$$\hat{\theta} = \sum_{i=1}^{n} (\hat{\alpha}_i - \widetilde{\alpha}_i) \mathbf{x}^{(i)}$$

Complementary slackness means:

$$\hat{\alpha}_i \left[\epsilon - y^{(i)} + \left(\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0 \right) \right] = 0 \quad \forall \ i \in \{1, ..., n\},$$

$$\tilde{\alpha}_i \left[\epsilon - \left(\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0 \right) + y^{(i)} \right] = 0 \quad \forall \ i \in \{1, ..., n\}.$$

So either $\hat{\alpha}_i = 0$, or $\hat{\alpha}_i > 0$, then $\epsilon = y^{(i)} - (\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0)$, and $(\mathbf{x}^{(i)}, y^{(i)})$ is exactly on the boundary of the ϵ -tube of the prediction and $\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0$ underestimates $y^{(i)}$ (by exactly ϵ). Similarly, it holds either $\widetilde{\hat{\alpha}}_i = 0$, or $\widetilde{\hat{\alpha}}_i > 0$, then $\epsilon = (\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0) - y^{(i)}$, and $(\mathbf{x}^{(i)}, y^{(i)})$ is exactly on the boundary of the ϵ -tube of the prediction and $\boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0$ overestimates $y^{(i)}$ (by exactly ϵ). For the bias term θ_0 we infer that

$$\theta_0 = y^{(i)} - \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} - \epsilon$$

in the case $\hat{\alpha}_i > 0$ and

$$\theta_0 = y^{(i)} - \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} + \epsilon$$

in the case $\tilde{\alpha}_i > 0$.

(e) The "softened" version of the optimization problem is obtained by introducing slack variables $\zeta^{(i)}, \widetilde{\zeta^{(i)}} \geq 0$ in the constraints:

$$\epsilon - y^{(i)} + \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} + \theta_0 \ge \zeta^{(i)} \quad \forall i \in \{1, \dots, n\}$$

and $\epsilon + y^{(i)} - \boldsymbol{\theta}^{\top} \mathbf{x}^{(i)} - \theta_0 > \widetilde{\zeta^{(i)}} \quad \forall i \in \{1, \dots, n\}.$

We minimize then a weighted sum of $\|\boldsymbol{\theta}\|^2$ and the sum of the slack variables:

$$\min_{\boldsymbol{\theta}, \theta_0} \quad \frac{1}{2} \|\boldsymbol{\theta}\|^2 + C \sum_{i=1}^n \zeta^{(i)} + \widetilde{\zeta^{(i)}}$$
s.t.
$$\epsilon - y^{(i)} + \boldsymbol{\theta}^\top \mathbf{x}^{(i)} + \theta_0 \ge -\zeta^{(i)} \quad \forall i \in \{1, \dots, n\}$$
and
$$\epsilon + y^{(i)} - \boldsymbol{\theta}^\top \mathbf{x}^{(i)} - \theta_0 \ge -\widetilde{\zeta^{(i)}} \quad \forall i \in \{1, \dots, n\},$$

$$\zeta^{(i)}, \widetilde{\zeta^{(i)}} \ge 0 \quad \forall i \in \{1, \dots, n\}.$$

(f) In the optimum, the inequalities will hold with equality (as we minimize the slacks), so $\zeta^{(i)} = \epsilon - y^{(i)} + \theta^{\top} \mathbf{x}^{(i)} + \theta_0$ and $\widetilde{\zeta^{(i)}} = \epsilon + y^{(i)} - \theta^{\top} \mathbf{x}^{(i)} - \theta_0$, but the lowest value $\zeta^{(i)}$ and $\widetilde{\zeta^{(i)}}$ can take is 0. So we can rewrite the above:

$$\frac{1}{2}\|\boldsymbol{\theta}\|^2 + C\sum_{i=1}^n L\left(y^{(i)}, f\left(\mathbf{x}^{(i)}\right)\right); \ L\left(y, f(\mathbf{x})\right) = \begin{cases} 0, & \text{if } |y - f(\mathbf{x})| \le \epsilon, \\ |y - f(\mathbf{x})| - \epsilon, & \text{else.} \end{cases}$$

This loss function is the ϵ -insensitive loss.

Solution 2: SVM - Optimization

• Implementation of the PEGASOS algorithm:

```
#' @param y outcome vector
#' Oparam X design matrix (including a column of 1s for the intercept)
\#' Oparam nr_iter number of iterations for the algorithm
#' Oparam theta starting values for thetas
#' Oparam lambda penalty parameter
#' Oparam alpha step size for weight decay
pegasos_linear <- function(</pre>
  Χ,
  nr_iter = 50000,
  theta = rnorm(ncol(X)),
  lambda = 1,
  alpha = 0.01)
  t <- 1
  n <- NROW(y)</pre>
  while(t <= nr_iter){</pre>
    f_{current} = X%*%theta
    i <- sample(1:n, 1)
    # update
    theta <- (1 - lambda * alpha) * theta
    # add second term if within margin
    if(y[i]*f_current[i] < 1) theta <- theta + alpha * y[i]*X[i,]</pre>
    t <- t + 1
  return(theta)
```

}
